Below is a listing of some of the medications commonly used for Recipients using Egg Donors, followed by a brief description for each type of medication.

(Please be aware that you may not use all of the medications listed. The exact medications you will use will depend upon the specific protocol decided upon by your physician.)

- **Subcutaneous Medications** (injected under the skin in the abdomen or thigh):
  - **Lupron**: A GnRHa agonist often used to temporarily “turn off” the ovaries.

- **Oral Medications**
  - **Doxycycline**: an antibiotic used by both partners during stimulation to reduce the chance of infection.
  - **Medrol**: is a corticosteroid used to prevent a potential negative immune response to the embryo(s).

- **Hormones**
  - **Estrogen tablets**: Estrace to stimulate endometrial lining thickness. May be administered orally or vaginally.
  - **Progesterone Support**: it is responsible for preparing the uterine endometrium for implantation. May be administered vaginally or via intramuscular injections.

NOTE: If you are pregnant, you will stay on progesterone and estrogen supplementation; however, if the pregnancy test is returned as negative, you would then stop this hormonal support.
